Experiment No.4

To implement the concept of block and blockchain using javascript

Date of Performance:

Date of Submission:

AIM: To implement the concept of block and blockchain using javascript

Objective: To develop a program, demonstrating the concept of block and blockchain

Theory:

Blocks are data structures within the blockchain database, where transaction data in a cryptocurrency blockchain are permanently recorded. A block records some or all of the most recent transactions not yet validated by the network. Once the data are validated, the block is closed. Then, a new block is created for new transactions to be entered into and validated.

A block is thus a permanent store of records that, once written, cannot be altered or removed.

A block stores information. There are many pieces of information included within a block, but it doesn't occupy a large amount of storage space. Blocks generally include these elements, but it might vary between different types:

- Magic number: A number containing specific values that identify that block as part of a particular cryptocurrency's network.
- Blocksize: Sets the size limit on the block so that only a specific amount of information can be written in it.
- Block header: Contains information about the block.
- Transaction counter: A number that represents how many transactions are stored in the block
- Transactions: A list of all of the transactions within a block.

The transaction element is the largest because it contains the most information. It is followed in storage size by the block header, which includes these sub-elements:

- Version: The cryptocurrency version being used.
- Previous block hash: Contains a hash (encrypted number) of the previous block's header.
- Hash Merkle root: Hash of transactions in the Merkle tree of the current block.
- Time: A timestamp to place the block in the blockchain.
- Bits: The difficulty rating of the target hash, signifying the difficulty in solving the nonce.
- Nonce: The encrypted number that a miner must solve to verify the block and close it.

Genesis Block

The genesis block is the first block of the blockchain. The genesis block is generally hardcoded in the applications that utilize its blockchain. The Genesis Block is also known as Block Zero or Block 0. It is an ancestor that every Blockchain network's block that can be traced to its origin back.

Blockchain

•

A blockchain in simple word is a database that stores and encrypts information in a linked fashion, so that previous information cannot be altered, and a group verifies any entries before they are finalized through a consensus—an agreement that the data is correct.

Blockchains are used in cryptocurrency, decentralized finance applications, non-fungible tokens, with more uses constantly under development.

Process:

- Step 1. Open the NetBeans IDE
- Step 2. Create new project of categories HTML/javascript and select Node.js application in the projects tab and click next
- Step 3. Give a suitable project name in the name and location tab and click next
- Step 4. Tick the Create Package.json in the Tools tab and click Finish
- Step 5. In the project directory under the source directory of the project create the required .js file

[block.js, blockchain.js, crypto-hash.js, genesis.js, server.js]

Step 6. Run the server is file, if no error then the resulting blockchain is created

Output:

```
Block (
 timestamp: 1694485274020, lastHash: 'c671c84681b9d682b9fd43b2a2ef0la343eab7cfa410df9835f8165007d38467',

```

Conclusion: Using JavaScript to create a block with its fields and form a blockchain can be justified for several reasons:

- Widespread Adoption: JavaScript is one of the most widely adopted programming languages, making it accessible to a large pool of developers, potentially lowering the barrier to entry for blockchain development.
- **Web Integration:** JavaScript is native to web development, allowing seamless integration of blockchain functionality into web applications, making it practical for decentralized web projects.
- **JavaScript Libraries:** There are JavaScript libraries and frameworks (e.g., Node.js) that simplify server-side scripting for blockchain interactions, facilitating blockchain development.
- Cross-Platform Compatibility: JavaScript can run on both the client and server sides, enabling end-to-end blockchain development and interactions with various platforms.
- Community and Resources: JavaScript has a vast and active developer community, resulting in extensive documentation, tutorials, and support for blockchain-related projects.
- **Rapid Prototyping:** JavaScript's flexibility allows for quick prototyping of blockchain concepts and experimentation, aiding in the development process.
- **JSON Compatibility:** JavaScript Object Notation (JSON) is natively supported in JavaScript, aligning well with blockchain data structures, which often use JSON for data representation.
- **Frontend Development:** For decentralized applications (DApps), JavaScript is crucial for building user interfaces and interacting with blockchain smart contracts on the frontend.
- **RESTful APIs:** JavaScript can be used to create RESTful APIs for blockchain interactions, enhancing interoperability with other systems.
